DETOXIFICATION AGENTS

The removal of toxic substances from organisms becomes essential when organs inadequately detoxify or excrete harmful substances. Dysfunction of organs such as liver and kidneys, as well as a disrupted intestinal barrier, is accompanied by the accumulation of substances like uremic and endogenous toxins or enterotoxins in the blood and tissue. This in turn triggers pathological processes that lead to e.g. chronic renal failure or gastrointestinal diseases. These common diseases are associated with an increased morbidity and overall mortality.

Removal of toxic substances is an important issue for numerous clinical indications. Therefore the development of effective and biocompatible sorbents to compensate organ dysfunction is a promising approach for the above mentioned indications.

Research into novel detoxification agents will help to expand the spectrum of therapeutic options and improve existing concepts.

The Project Group Extracorporeal Immuno-modulation develops in vitro screening models and test systems for the evaluation of innovative sorbents and detoxifying agents.

Focus

Our current research activities focus on members of the silicate and smectite group of clay minerals. These substances display unique adsorption characteristics, which make them very promising candidates for various detoxification challenges.

Specific in vitro tests reveal the potential for the binding of relevant harmful substances like uremic toxins, as well as entero- and bacterial endotoxins, as could be shown for Montmorillonite illite clay minerals. These findings could also be verified in subsequent in vivo screenings.
Inflammatory bowel disease

Inflammatory bowel disease (IBD) is a chronic relapsing inflammatory condition of the gastrointestinal tract. IBD patients need lifelong medication which often leads to serious side effects. Therefore treatment of IBD and the exploration of novel therapies represent an important research field.

We established a short-time-intestinal-bowel model that could serve as an experimental test system which enables the investigation of early mucosal inflammation of IBD pathogenesis and the rapid screening of novel therapeutic options.

Examination of smectite clay minerals in our short-time model as well as in an acute dextran sodium sulfate (DSS)-induced model proved their beneficial effects on inflammatory processes. Furthermore, prophylactic smectite application could alleviate the clinical signs of DSS-induced colitis, possibly mediated by barrier strengthening processes and intestinal microbiome modification.

These studies indicated smectites as a novel therapeutic and prophylactic option for IBD-treatment.

Chronic renal failure

Chronic kidney disease (CKD) is highly associated with elevated serum phosphate levels contributing to vascular calcification and an increased cardiovascular risk in dialysis patients. Reduction of hyperphosphatemia is the main therapeutic target and the finding of novel phosphate binding agents is an essential research area.

We investigated the phosphate binding capacity of modified, highly phosphate affine smectites and their impact on phosphate induced cellular calcification processes in an in vitro cell culture model of human coronary artery smooth muscle cells. Furthermore, application of phosphate adsorbing smectites in a rat model of CKD resulted in (i) significantly reduced pathology in their vasculature, (ii) lowered microalbuminuria, which is a prognostic marker for cardiovascular events and (iii) finally increased the survival of renal insufficient rats.

Due to the high phosphate affinity of smectites and the resulting lowered vascular pathology in CKD rats, this study indicates smectite as potent phosphate absorber, comparable to established clinical therapeutics.

Equipment

The Fraunhofer Project Group for Extracorporeal Immunomodulation is well equipped for the characterization of detoxifying agents:

- Cell culture facilities
- Animal models
- Histology equipment
- Fluorescence microscopy

Due to a broad network of cooperation partners, the group also has access to additional state-of-the-art technologies. Furthermore, the cooperation with different clinical departments (like gastroenterology, nephrology, microbiology) of the University of Rostock allows a clinically oriented research of new therapeutic strategies.

IP situation

We patented the use of mineral compounds for the application in inflammatory bowel disease and for the reduction of serum phosphate caused by chronic renal failure.
